# PWC-Net: CNNs for Optical Flow Using Pyramid, Warping, and Cost Volume Supplementary Material 

Deqing Sun, Xiaodong Yang, Ming-Yu Liu, and Jan Kautz NVIDIA

Section 1 provides more ablation and visual results. Section 2 summarizes the details of our network. Section 3 shows the screenshot of the MPI Sintel final pass, KITTI 2012, and KITTI 2015 public tables at the time of submission (November 15th, 2017). Section 4 shows the learned features at the first level of the feature pyramid extractor.

## 1. More Ablation and Visual Results

Figure 1 shows the enlarged images of Figure 1 in the main manuscript. PWC-Net outperforms all published methods on the MPI Sintel final pass benchmark in both accuracy and running time. It also reaches the best balance between size and accuracy among existing end-to-end CNN models.

Table 1 shows more ablation results, in particular, the full results for models trained on FlyingChairs (Table 1a) and then fine-tuned on FlyingThings3D (Table 1b). To further test the dilated convolutions, we replace the dilated convolutions of the context network with plain convolutions. Using plain convolutions has worse performance on Chairs and Sintel, and is slightly better on KITTI. We also have independent runs of the same PWC-Net that only differ in the random initialization. As shown in Table 1d, the two independent runs lead to models that have close performances, although not exactly the same.

Figures 2 and 3 provide more visual results by PWCNet on the MPI Sintel final pass and KITTI 2015 test sets. PWC-Net can recover sharp motion boundaries in the presence of large motion, severe occlusions, and strong shadow and atmospheric effects. However, PWC-Net tends to produce errors on objects with thin structures that rarely occur in the training set, such as the wheels of the bicycle in the third row of Figure 3.

## 2. Network Details

Figure 4 shows the architecture for the 7-level feature pyramid extractor network used in our experiment. Note that the bottom level consists of the original input images. Figure 5 shows the optical flow estimator network at pyramid level 2. The optical flow estimator networks at other
levels have the same structure except for the top level, which does not have the upsampled optical flow and directly computes cost volume using features of the first and second images. Figure 6 shows the context network that is adopted only at pyramid level 2.

## 3. Screenshots of MPI Sintel and KITTI Public Table

Figures 7-9 respectively show the screenshots of the MPI Sintel final pass, KITTI 2015, and KITTI 2012 public tables at the time of submission (November 15th, 2017). Among all optical flow methods, PWC-Net is ranked 1st on both MPI Sintel final and KITTI 2015, and 2nd on KITTI 2012. Note that the 1st-ranked method on KITTI 2012, SDF [1], assumes a rigidity constraint for the background, which is well-suited to the static scenes in KITTI 2012. PWC-Net performs better than SDF on KITTI 2015 that contains dynamic objects and is more challenging.

## 4. Learned Features

Figure 10 shows the learned filters for the first convolution layer by PWC-Net and the feature responses to an input image. These filters tend to focus on regions of different properties in the input image. After training on FlyingChairs, fine-tuning on FlyingThings3D and Sintel does not change these filters much.

(d) Two independent runs result in slightly different models.

Table 1. More ablation experiments. Unless explicitly stated, the models have been trained on the FlyingChairs dataset.

Estimated optical flow

Esflmated optlcal flow

Figure 2. More PWC-Net results on the MPI Sintel final pass dataset.

Figure 3. More PWC-Net results on KITTI 2015 test set. PWC-Net can recover sharp motion boundaries despite large motion, strong shadows, and severe occlusions. Thin structures, such as the bicycle, are challenging to PWC-Net, probably because the training set has no training samples of bicycles.

Figure 4. The feature pyramid extractor network. The first image $(t=1)$ and the second image $(t=2)$ are encoded using the same Siamese network. Each convolution is followed by a leaky ReLU unit. The convolutional layer and the $\times 2$ downsampling layer at each level is implemented using a single convolutional layer with a stride of 2. $\mathbf{c}_{t}^{l}$ denotes extracted features of image $t$ at level $l$;

Figure 5. The optical flow estimator network at pyramid level 2. Each convolutional layer is followed by a leaky ReLU unit except the last (light green) one that outputs the optical flow.

Figure 6. The context network at pyramid level 2. Each convolutional layer is followed by a leaky ReLU unit except the last (light green) one that outputs the optical flow. The last number in each convolutional layer denotes the dilation constant.

Figure 9．Screenshot of the KITTI 2012 public table．SDF［1］is the only optical flow method that has lower percentage of outliers in non－occluded regions（Out－Noc）than PWC－Net．However，SDF assumes a rigidity constraint for the background，which is well－suited for the static scenes in the KITTI 2012 set．

(a) Learned filters

(c) Feature responses

Figure 10. Learned filters at the first convolutional layer of PWC-Net and the filter responses to an input image.
